

TEX-207-F, PART III

Determining In-Place Density (Nuclear Method)

Why

Determine the in-place density of compacted hot mix asphalt using a nuclear density testing gauge.

Accurate measurement of density will ensure adequate density of hot mix asphalt will be acheived. This will produce a less permeable, smooth, and stable roadway.

When

Measure in-place density to establish rolling patterns at the start of placement, anytime during roller compaction, or whenever there is a change in production or thickness of the mat or roadway conditions.

How

Equipment

- Nuclear Density Gauge
 - · Lift thickness two inches or less
 - Thin layer or thin lift gauge
 - Backscatter Mode
 - Lift thickness greater than two inches
 - Direct transmission Mode
- Ensure all applicable regulatory certifications are current and requirements are met.
- Follow the manufacturer's instructions and recommendations for calibration, operation, maintenance, and standardization procedures.
- Portable Reference Standard (Standard Block Supplied with the Gauge)
- Scraper Plate and Drill Rod Guide
- Drill Rod and Driver or Hammer
- Shovel, Sieve, Trowel, Straightedge, Miscellaneous Hand Tools.
- Construction Marker Paint or Crayon
- Gauge Logbook

Standardization

- Perform daily when the gauge is used.
 - This will determine if the gauge is working properly.
- Turn on the nuclear density gauge and allow it to warm up and stabilize.
- · Allow at least 10 minutes.
- Perform at least 25 feet away from other sources of radioactivity on a smooth and dry asphalt surface.
 - The preferred area is the roadway location. This is best to determine day-to-day variability of the gauge.
- Take a minimum of four repetitive readings of four minutes for each reading.

Standardization Results

- When the values from the standardization count are within acceptable limits.
 - o Gauge is considered to be in satisfactory operating condition and may be used for the day of use.
- When the values from the standardization count are outside of acceptable limits.
 - Allow additional time for the gauge to stabilize, make sure area is clear of sources of interference, then
 conduct another standardization.
- When the values from the second standardization count are within limits.
 - Gauge may be used.
- When the values from the second standardization count also fails the test.
 - Gauge may not be used and must be adjusted or repaired as recommended by manufacturer.

Procedure

- 1. Select an area free of loose material, voids, or depressions.
 - Select an area at least 12 inches away from obstructions, such as curbing.
 - It is optional to use fine sand to fill any voids or minor depressions.
- 2. Firmly seat the gauge on the selected area so it is in full contact with the surface.
 - When the surface is hot, do not leave the gauge on the mat for a long time as erratic readings may result from the hot surface.
- 3. When thickness is greater than two inches, use a gauge in direct transmission mode.
 - Use the drive pin and guide plate to make a hole into the mat. It may be necessary to drill the hole.
 - Make a hole as close as possible to 90 degrees from the plane surface.
 - Make the hole two inches deeper than the lift thickness.
 - Lower the handle to the bottom of the lift.
- 4. Measure the density of the compacted mat.
- 5. Determine the density of the tested area.
 - Models are programmable to provide direct readings of density or percent compaction (air voids).
 - Divide the field counts by the standard counts.
 - When necessary, use appropriate calibration curves.
- 6. Hydrocarbons from the asphalt may influence results and not produce accurate values compared with the actual density measured from roadway cores.
- 7. When more accurate results are needed, determine a correlation factor for gauge readings using the bulk specific gravity of roadway cores.
 - Use a minimum of seven core densities and seven nuclear gauge readings.
